

# **Formula for Quoting Complete Sets of Distribution Boxes**

## Overview

---

Simple probabilistic modeling shows that on average  $(n(1 + 1/2 + \dots + 1/n))$  boxes are required to complete a full set of  $(n)$  prizes: for example, it takes on average 14. Distributing identical items into different boxes, where some boxes can be empty. Understanding these cases helps students solve Permutations and Combinations problems more easily and accurately. Additionally, the pallet number should show values 1, 2, 3, or 4, with a link to cell M8 for displaying pallet. It is given that this formula can be proved using principle of inclusions and exclusion and using set theory, but how?

Edit: This formula is also used to find the number of onto functions from a  $A$  with  $|A|=n$  to  $B$  with  $|B|=r$ . When identical objects are distributed among persons, the only thing that matters is who is getting how many objects.
