

Working principle of dual optical ports in a switch

Overview

When two ports need to communicate, the controller configures a path in the optical switch matrix, using optical components to route the optical signal from one fiber to another, forming an. These devices play a critical role in modern optical networks by enabling dynamic reconfiguration, wavelength routing, and protection switching. Optical switching is the process of controlling the destination of individual optical information signals. Initially, digital systems used Time Division Multiplexing (TDM), which broke different voice or data signals into pieces and sent them in alternating slots in one stream.
